

Establishing Legion as a Cross-Platform Reputation Layer in Web3 and Web2

Legion is a crypto-native reputational platform aiming to become a foundational “reputation layer” across decentralized Web3 systems and traditional Web2 applications. To achieve structural importance, Legion must integrate technically with existing protocols, bridge identity standards, and embed within ecosystem infrastructure—all while preserving privacy and a low-key branding (AbsurdSenapiii Labs) presence. Below, we explore concrete pathways for Legion’s integration, focusing on what is technically feasible today and in the near future.

Integrating Legion into Decentralized Web3 Protocols

Legion can add value to major Web3 domains by providing a portable, merit-based reputation that protocols trust. The key technical approach is to make Legion Scores and credentials easily accessible (via on-chain contracts, SDKs, or APIs) so that DeFi platforms, DAOs, NFT marketplaces, Layer-2 chains, and governance tools can **incorporate reputation data into their logic**. Potential integration pathways include:

- **DeFi Credit and Lending:** DeFi lending platforms can use Legion as an on-chain credit scoring oracle for under-collateralized or reputation-based loans. A borrower’s Legion Score (or specific **financial reputation credentials**) could allow dynamic loan terms (e.g. lower collateral or interest for high-rep users) ¹ ². Smart contracts could query Legion’s contracts or an attestation of creditworthiness to decide loan eligibility. For example, Orange Protocol’s system shows that aggregating on-chain history and behavior into a trust score enables under-collateralized lending by **weighing transaction history, liquidity, and repayment habits** ² ³. Legion could similarly provide a composable credit reputation that **DeFi protocols read on-chain or via an oracle**, unlocking more humanized finance in Web3.
- **DAO Governance and Contributions:** DAOs struggle to measure contributor reputation when all they see is a wallet address. Legion can integrate by offering **reputation-weighted voting** and contributor credentialing. For instance, DAOs using off-chain voting (Snapshot) could plug in a custom strategy that multiplies voting power by a member’s Legion Score or badges, rewarding proven contributors over newcomers. Snapshot already supports custom voting strategies via plugins ⁴, so a Legion strategy could be feasible. On-chain governance frameworks (like Optimism’s governance or Aragon) could likewise read Legion attestations: e.g. require a minimum reputation to propose an action or weight votes quadratically by reputation to reduce plutocracy. This aligns with the **vision of moving beyond token-only governance to human-centric metrics** ⁵. Legion’s data (e.g. a history of DAO contributions, completed bounties, or leadership roles) can be issued as verifiable credentials and used to **immediately trust new contributors** in a DAO ⁶ ⁷. By making DAO membership **reputation-aware**, Legion helps communities recognize and empower those who have demonstrated value.
- **NFT Platforms and Marketplaces:** Reputation can enhance NFT ecosystems by distinguishing genuine creators/collectors from spammers or fraudsters. Legion could integrate with marketplaces (like OpenSea or Blur) via APIs or contracts to display **“Legion Verified” badges** on

seller profiles, indicating a history of positive contributions (e.g. helpful community presence, prior successful projects). Much like Web2 marketplaces have seller ratings, a marketplace could **query a wallet's Legion Score and credentials** before allowing high-value trades or featuring listings. For creators, Legion might offer NFT-specific reputation credentials (e.g. an artist's verified contributions or collector following) to help platforms promote trustworthy content. Technically, this requires Legion to provide endpoints or on-chain data that marketplaces can fetch in real-time (for instance, a contract mapping an address to a reputation score or an API that returns profile data). Because on-chain assets and credentials are publicly verifiable ⁸, **NFT platforms can trust Legion's on-chain attestations** of authenticity or provenance. This could reduce scams by flagging addresses with low reputation or known sybil behavior.

- **Layer-2 Chains and Protocol Infrastructure:** Legion can become part of the **identity layer of L2s and dApp chains** by leveraging emerging standards on those networks. For example, Optimism's **AttestationStation** on OP Mainnet is a neutral, permissionless contract where anyone can publish reputation attestations about addresses ⁹. Legion could publish reputation data (scores or tags) into such contracts, making itself part of the base **reputation graph** on these chains. This means any new OP Stack chain (which now comes with the Ethereum Attestation Service integrated at genesis ¹⁰) would automatically include Legion's contributions as a data source. L2 projects focused on public goods or identity could adopt Legion if it presents as **open infrastructure**: e.g. an L2 could use Legion credentials to identify unique humans for one-person-one-vote governance (similar to Optimism's "Citizens' House" model of using identity instead of tokens for voting ¹¹). Technically, Legion might deploy its contracts on major L2s (Arbitrum, Optimism, Base, etc.) to make querying reputation **cheap and fast**, or use cross-chain bridges to **carry reputation data across networks** ¹² ¹³. Indeed, Legion has already expanded to multi-chain: it operates across Ethereum and Solana and focuses on Arbitrum for EVM integration ¹⁴. Ensuring each chain can easily consume Legion data (via standardized attestations or an SDK) will entrench Legion as the go-to reputation provider at the protocol level.

- **Governance Stacks and Tooling:** Beyond raw blockchains, Legion can integrate with governance apps and developer tools. This could include plugins for **common DAO tools** (Snapshot, Tally, Boardroom) so that whenever a community holds a vote or distributes roles, they have the option to incorporate Legion's reputation signals. For instance, Snapshot's flexible strategy system could use Legion's API to fetch a voter's score or check for certain **non-transferable tokens (badges) issued by Legion** that denote reputation. Similarly, forums or community platforms (Commonwealth, Discord bots, Discourse forums) could use Legion's credentials to display a user's Web3 reputation next to their username. From a technical standpoint, Legion would offer a **simple API/SDK** that developers can call with an address (or DID) to retrieve reputation metrics ¹⁵ ¹⁶. The Orange Protocol example highlights this approach: they provide REST APIs, JS SDKs, and smart contract libraries to let devs **pull in reputation data on the fly** ¹⁶. Legion can emulate this by offering easy integration kits – for example, a one-line code snippet for "LegionScore.lookup(address)" – to be used in governance UIs or dApps. By lowering integration effort, Legion can quickly proliferate across the Web3 tooling landscape.

Technical Feasibility: All the above integrations rely on technology that exists today: on-chain data contracts, verifiable credentials, and API access. Projects like **Bitcoin Passport** and **Orange Protocol** have demonstrated that aggregating multi-platform data into a trust score can directly feed into dApps (for sybil-resistant voting, lending, etc.) ¹ ². Snapshot already allows external scoring logic in votes, and Optimism's AttestationStation shows on-chain reputation graphs are viable ¹⁷. The main work for Legion is to **package its reputation engine outputs for composability** – e.g. publishing scores on-

chain, issuing W3C credentials, and providing dev-friendly interfaces. By doing so, Legion's merit-based score (which already considers social, on-chain and technical contributions ¹⁸ ¹⁹) can become a plug-and-play module for any Web3 protocol that needs trust signals.

Bridging Legion to Web2 Identity Systems

To be relevant beyond Web3, Legion should bridge into the Web2 ecosystem of logins, profiles, and credentials. This means integrating with **existing Web2 identity flows (OAuth, SSO)**, leveraging **W3C standards for verified credentials**, and pulling data from Web2 platforms to enrich crypto identities. Several strategies can make Legion a two-way bridge between Web3 and Web2:

- **OAuth & Single Sign-On Integration:** A powerful approach is for Legion to function as an **OpenID Connect (OIDC)** identity provider that Web2 apps can use for login. In practice, this could look like a "Sign in with Legion" button alongside Google or Facebook login. Users would authenticate via their crypto wallet (proving control of an address/DID) and Legion would provide an OIDC token containing claims about their identity and reputation. This is technically feasible today: the **Sign-In with Ethereum (SIWE)** standard (EIP-4361) has been adapted into an OIDC provider by projects like SpruceID ²⁰. In fact, Auth0 (a mainstream authentication platform) already added support for SIWE in 2022, allowing users to log in to traditional apps with an Ethereum wallet ²¹. Legion can piggyback on this trend by offering its users a way to **log in to Web2 services using their Legion profile** – effectively acting as a decentralized "single sign-on" service. The difference from a pure SIWE login is that Legion can attach **reputation claims** to the identity. For example, when a user logs in via Legion, the OIDC token could include claims like "LegionScore: 750" or specific badges (skills, verification status) as part of the user profile. Web2 applications (forums, marketplaces, even enterprise apps) could then use these claims for access control or user vetting. Since Auth0's integration already can fetch ENS profiles and include them in ID tokens ²² ²³, a similar pattern could be extended to **Legion's data** – e.g. providing a user's verified ENS name, avatar, and Legion reputation in one package. By aligning with OAuth/OIDC, Legion makes itself easy to adopt in Web2: any developer familiar with Google/Facebook login can now accept Legion for a "crypto-enhanced" login experience.
- **Verified Credentials (VCs) for Real-World Identity:** Legion should leverage W3C **Verifiable Credentials** to represent reputation and identity data in a standard format that companies and institutions recognize. VCs are cryptographically signed attestations (e.g. "X has skill Y", "X contributed to project Z") that users can present as proof ²⁴. Legion can issue VCs to users for aspects of their reputation – for instance, a "**Legion Reputation Certificate**" that summarizes a user's contributions, or more granular credentials like "Certified Web3 Developer" if their GitHub Dev Score is high. These credentials, backed by Legion (AbsurdSenapiii Labs) as the issuer, could be shared with Web2 entities: for example, a user could attach a Legion-issued credential to their LinkedIn profile or job application to prove their Web3 community standing. Technically, this requires Legion to run a DID (Decentralized Identifier) method or use an existing one (did:eth or did:web) to sign credentials. Many platforms (including Microsoft Entra and other enterprise IAM systems) are beginning to support verifying W3C credentials ²⁵. By issuing standards-compliant credentials, Legion makes its reputation **portable outside the crypto bubble** – a developer could log into a coding platform and present a Legion VC that confirms "Top 5% on Dev Score" as an achievement, which the platform could verify without needing to query blockchains. This bridge builds credibility for Legion in the Web2 world by **piggybacking on emerging decentralized ID frameworks**. In essence, Legion would serve as a **credential provider** in the broader identity ecosystem, similar to how universities issue digital diplomas or how LinkedIn might issue work verification badges. The credibility of these credentials would grow as Legion

partners with known entities (for example, if a tech conference accepts a Legion credential to grant a speaker role, it reinforces Legion's authority).

- **Integration with Developer & Social Platforms:** Legion's scoring model already taps into Web2 platforms – e.g. it evaluates **social influence (Twitter, Discord)** and **developer activity (GitHub)** as part of the score ²⁶ ²⁷. To deepen this, Legion should implement robust account linking and data integration for major Web2 networks:
 - *Twitter/X and Discord:* Legion can use OAuth flows to let users verify their social accounts. For example, a user could connect Twitter by signing a message or through **zk-proofs of follower count** (techniques exist to attest “I have $\geq N$ followers” without revealing exact followers ²⁸ ²⁹). Discord integration might involve a Legion bot that verifies a user's wallet (many DAOs already use bots to link Discord IDs to Ethereum addresses). Once linked, Legion can **pull engagement metrics** (tweets, likes, Discord roles) via APIs or accepted proofs, feeding into reputation. The **Orange Protocol** illustrates this by letting users link socials via a browser extension and increasing their **Humanity Score** with each verified account ³⁰ ³¹. Legion could similarly allow multiple Web2 verifications (without storing any private data on-chain) to enrich its scoring of “social capital”.
 - *GitHub and Developer Hubs:* Given Legion's “Dev Score” component, direct integration with GitHub's API or badging systems is key. Legion can have users verify ownership of a GitHub account (for instance, by signing in with GitHub OAuth during Legion onboarding). After linking, Legion can continuously fetch key metrics: contributions frequency, stars, participation in known Web3 repos, etc. This data can update the user's reputation credentials. Moreover, Legion could collaborate with GitHub or platforms like StackOverflow to issue **verifiable attestations of developer achievements**. Technically, this could mean using **GitHub Actions** or webhooks to trigger Legion to update a credential when a user's pull request is merged in a major project (creating an attestation like “contributed code to Uniswap”). By bridging these, Legion positions itself as a **developer reputation layer** connecting Web2 coding profiles with Web3 opportunities.
 - *Professional Networks (LinkedIn) and Credentials:* Though more challenging due to closed ecosystems, Legion could leverage LinkedIn's verified credential initiative (Microsoft's Entra Verified ID) to both consume and provide data. For example, if a user has a verified credential from a university or employer (via LinkedIn or Entra), Legion could allow the user to import that as part of their profile (with consent). Conversely, Legion might issue a summary of the user's Web3 reputation that could be displayed on their LinkedIn via a badge or link. While this is more forward-looking, the technology is coming together – LinkedIn has piloted **digital credential sharing for work achievements** ³². By staying aligned with these developments, Legion ensures its reputation data can flow into professional contexts, effectively **bridging the trust gap** between Web3 pseudonymous accomplishments and real-world identity.
- **Use of ENS for Cross-Platform Identity:** Ethereum Name Service (ENS) can serve as a linchpin between Web3 and Web2 identity. Many Web3 users already have ENS names (e.g. `alice.eth`) which can store profile information like avatars, websites, or Twitter handles in text records. ENS names are themselves **DIDs** (did:ens) and **Web3 usernames** ³³ ³⁴. Legion can leverage ENS in two ways. First, **identity linking:** Encourage or require users to have an ENS name associated with their Legion profile (perhaps offer ENS subdomains as part of Legion onboarding). This gives a human-readable identity that Web2 apps can display. Second, **ENS profile integration:** Legion could populate ENS records with certain reputation data – for example, writing a “legion.score” text record to a user's ENS profile. Already, Auth0's ENS integration shows that when a user signs in with Ethereum, an app can fetch their ENS profile (name, avatar, etc.) and

use it in a Web2 context ²². If Legion adds reputation info to that profile, **any app retrieving ENS data via Auth0 or other means would immediately get a Legion reputation snippet as well**. This effectively watermarks a user's cross-app identity with Legion's data. The beauty of ENS is that it's widely adopted (nearly 2M names) and **recognized in both Web3 and Web2 developer communities** ³³. By integrating here, Legion's reputation layer becomes part of the **"login with Ethereum" experience**. For instance, when Alice uses her `alice.eth` to sign in somewhere, the app not only sees a username but also (if permitted) sees that Alice has, say, a Legion Score of 800 and an "NFT Artist" credential. This **blurs the line between Web2 and Web3 identity** in a seamless, technically standardized way.

In summary, bridging to Web2 requires Legion to speak the language of Web2 auth (OAuth, OIDC), **adhere to identity standards (DIDs, VCs)**, and integrate with popular platforms via APIs or plugins. The technical pieces are largely in place: the **W3C DID/VC framework** is mature ³⁵ ³⁶, projects like Auth0, Spruce, and Gitcoin Passport have paved the way for wallet-based logins and credentials in Web2 ²¹ ³⁷. Legion's task is to package its reputation system as an **identity provider and credential issuer**. By doing so, it can inject crypto-native reputation into Web2 contexts ranging from hiring and social networking to e-commerce (imagine a seller on eBay linking their Legion trust score to prove they are a reputable crypto community member). All of this enhances Legion's **influence and utility beyond the crypto niche**, making it structurally important in the broader digital identity landscape.

Federation and Standards Alignment (DID, VCs, ENS, etc.)

To avoid being a siloed service, Legion should align with decentralized identity standards and participate in federated identity networks. Embracing standards ensures Legion can be **embedded within other identity systems** rather than competing in isolation. Key standards and how Legion can position itself:

Standard / Ecosystem	Legion's Alignment Strategy
Decentralized Identifiers (DID) W3C standard for unique, self-controlled IDs ³⁸	Use DIDs to represent Legion user identities. For example, each user's Ethereum address can be associated with a DID (e.g. did:pkh:eth or a custom did:legion: method) controlled by their keys. This DID can be the anchor for all reputation data. Legion should resolve DID documents that list the user's associated keys and perhaps links to their ENS, etc. By adopting DIDs, Legion becomes <i>chain-agnostic</i> – a user's DID can link to Ethereum, Solana, and other accounts ³⁸ , matching Legion's multi-chain approach. It also allows interoperability: other apps can reference the DID to fetch Legion credentials without directly using Legion's proprietary ID. In effect, Legion would join the broader DID ecosystem (e.g. participating in DIF – Decentralized Identity Foundation) so that its identities are recognized across platforms.

Standard / Ecosystem	Legion's Alignment Strategy
Verifiable Credentials (VC) <i>
W3C standard for signed attestations</i> ²⁴	Issue and accept credentials in VC format. Legion can act as a credential issuer, signing claims like "GitHubContributorLevel: Gold" or "LegionScore: 720" that users store in their wallet or identity hub. These credentials are portable and verify that "AbsurdSenapiii Labs attests X". Legion should also build in a VC verification service – meaning it can ingest credentials from others (e.g. a college degree, a BrightID "unique person" proof) as part of a user's profile. Embracing VCs allows Legion to plug into emerging frameworks (for instance, a user could add their Legion VC to a Microsoft Entra Verified ID wallet or present it to an OAuth provider that supports VC login). Technically, Legion would maintain a public DID for issuing (so verifiers can fetch its public key) and likely use JSON-LD or JWT-based credentials for compatibility. This standardization moves Legion from a closed scoring system to a credentials platform that others can trust and build upon ³⁹ ⁴⁰ .
ENS (Ethereum Name Service) <i>
Decentralized name system serving as Web3 ID</i>	Leverage ENS as a profile hub for Legion users. ENS allows storing text records and content hashes on profiles; Legion could define a standard ENS record schema for reputation data (e.g. a short fingerprint of one's Legion Score or a URL to a Legion-hosted credential). By doing so, any ENS-integrated app (wallets, explorers, etc.) can display aspects of Legion reputation by simply resolving the ENS name. Additionally, ENS subdomains could be used to federate identity: for example, Legion might give each user an ENS subdomain like <code>user123.legion.eth</code> linked to their main identity, which can serve as a unified alias across Web3. ENS names are now recognized as valid DIDs and Web2 usernames (see Auth0 integration) ³⁴ ²² , so tying Legion to ENS strengthens its ubiquity. Legion might even collaborate with ENS DAO to make "reputation records" a common use case of ENS, positioning Legion as the provider of reputation data for ENS profiles.

Attestation Networks (EAS, AttestationStation)
On-chain public attestation layers

Contribute and utilize decentralized attestation layers instead of only proprietary data stores. The **Ethereum Attestation Service (EAS)** and Optimism's AttestationStation provide generalized, chain-agnostic ways to record attestations (which can represent DID claims, VCs, or custom scores) ³⁹ ⁹ . Legion can define one or more **attestation schemas** in EAS – for instance, a schema for “LegionScore” which takes an integer value and an expiration. Legion's backend (or contracts) could then publish attestations to EAS for each user, periodically updating their score or specific achievement tags. Because EAS is permissionless, anyone (including Legion) can write attestations that any app can read from the blockchain. This makes Legion's data **a public good accessible to all dApps, not just via Legion's API** ¹⁷ . It also invites **federation** – other parties could also write attestations under Legion's schema (if Legion chooses to open it), or Legion could ingest attestations others have made (with appropriate trust checks). For example, if a DAO attests that Alice was a top contributor in season 1, that attestation on Optimism could be picked up by Legion to boost Alice's score. Using the attestation graph also enables web-of-trust computations (the Optimism team mentions running EigenTrust-like algorithms over AttestationStation data) ⁴¹ , which aligns with Legion's own EigenTrust-based approach. In short, by participating in on-chain attestation networks, Legion ensures its reputation layer is **composable and decentralized**, increasing its structural importance as part of the Ethereum/OP Stack identity fabric.

Soulbound Tokens (SBTs)
Non-transferable tokens for identity/reputation

Consider SBTs or **account-bound NFTs** as an implementation for some credentials – but cautiously. An SBT could represent a fixed achievement or role (e.g. “Legion Top 100 Member 2025” as a badge NFT that can't be sold). This would allow easy on-chain verification of certain reputational milestones and could be displayed in wallets. However, Legion should use SBTs only for *public, non-sensitive* credentials (given privacy concerns with permanent on-chain data) ⁴² ⁴³ . For more granular rep info, off-chain VCs or EAS attestations (which can be revoked or kept semi-private) are preferable ⁴⁴ . If used, Legion's SBTs should conform to emerging standards (e.g. ERC-5727 or other account-bound token standards) to ensure compatibility with wallets and explorers. By issuing any SBTs, Legion would effectively be watermarking user addresses with a **public “stamp” of reputation** that any protocol can check. This might boost adoption in scenarios where on-chain proof is needed (like a DeFi pool that only whitelists addresses holding a certain Legion badge). The key is to align with community best practices for SBTs and perhaps support the idea that **signed claims (VCs/ attestations) are often better than permanent tokens** for reputation ⁴² .

Overall, Legion's adherence to these standards will position it not as a black-box service but as a **participant in the decentralized identity ecosystem**. Using DIDs abstracts away blockchain addresses into a unified identity ³⁶, VCs provide interoperable and privacy-preserving credentials, and ENS and EAS make Legion's data accessible broadly in user-friendly ways. This federated approach is technically achievable now: the standards are in place and projects are adopting them (e.g. Bitcoin Passport uses Ceramic and EAS to turn Web2 verifications into on-chain attestations) ⁴⁵ ⁴⁶. By aligning with them, Legion ensures that as the Web3 identity stack coalesces, Legion will be **the reputation layer plugged into everyone else's identity layer**. This structural ubiquity is far more defensible than a standalone app.

Synergies with Zero-Knowledge Proofs, Attestations, and On-Chain Reputation Mechanics

An important technical dimension for Legion is preserving privacy and security while scaling trust. **Zero-knowledge proofs (ZKPs)** and **cryptographic attestations** can allow Legion to provide reputation information without revealing sensitive underlying data. Additionally, embracing novel on-chain reputation mechanics (like web-of-trust algorithms and non-transferable tokens) can enhance Legion's credibility and adoption. Several synergies stand out:

- **Privacy-Preserving Reputation via ZK Proofs:** Legion's reputation model aggregates data from many sources – some of which may be sensitive (e.g. a user's total bank exchange balance, or their social connections). Using zero-knowledge techniques, Legion can prove statements about a user *without disclosing raw data*. For example, Legion might use zk-SNARKs or similar to let a user prove **"My Twitter account has over 5k followers"** or **"I have never been liquidated in DeFi loans"** to Legion's system, which in turn boosts their score, all without exposing their actual follower list or financial details. Projects like Orange Protocol have pioneered such approaches with *zkTLS*, a system for verifying Web2 account data privately ²⁸ ²⁹. In Orange's case, zkTLS allows verifying things like Twitter or Discord account ownership and certain thresholds (follower count, account age) using ZK proofs so that only a yes/no or threshold result is revealed ⁴⁷. Legion could adopt a similar method: when linking Web2 accounts or off-chain data, use ZK circuits to validate the data and then issue an attestation that "conditions X, Y, Z are met" with zero knowledge. Furthermore, ZKPs can enable **selective disclosure** of reputation. Instead of revealing a raw Legion Score to every dApp (which might deanonymize a user or expose them to bias), Legion could allow users to generate a ZK proof that **"My Legion Score is above 600"** or **"I have the Gold Contributor credential"** *without revealing anything else*. This would involve creating circuits that take the user's credential and a secret (their score) and outputs a proof of the predicate. The technology for such proofs exists in prototype (e.g. ZK-STARKs for proving attributes of credentials, as used in Polygon ID and similar systems). By building ZK support, Legion aligns with the privacy ethos of Web3 and makes itself viable in contexts like DeFi or identity where anonymity is valued. A concrete near-term synergy could be partnering with a ZK-identity project (like Sismo or Polygon ID) to incorporate Legion data into their proof generation – for instance, Sismo "badges" could be minted based on a ZK proof of one's Legion Score tier, letting users prove reputation on-chain while keeping details hidden.
- **On-Chain Attestations and Web-of-Trust Algorithms:** As mentioned, Legion can publish attestations on-chain for openness. But beyond publishing, Legion can harness *peer attestations* to enrich its scoring. Consider that Legion might not know every nuance of a user's behavior, but other community members might. If Legion accepts community attestations (through a controlled scheme to prevent spam), it could feed these into its EigenTrust-based algorithm to compute a more nuanced reputation ⁴¹ ⁴⁸. EigenTrust, originally for P2P networks, computes

global trust scores by propagating trust through a graph of local ratings ⁴⁹ ⁵⁰ . Legion already uses EigenTrust principles internally to make its scores abuse-resistant ⁵¹ . By moving some of that model on-chain or into a decentralized graph, Legion could become *less of a unilateral oracle* and more of a **facilitator of a web-of-trust**. For example, Legion could allow verified DAO treasuries or project teams to write **Endorsement attestations** (similar to its current Endorsement Score mechanic where teams rate purchasers) ⁵² directly to a public contract. Legion’s algorithm could then aggregate these in a transparent way. This not only improves resilience (harder for one entity to manipulate the system) but also increases adoption: communities might feel **ownership in Legion’s reputation system** if they can contribute attestations to it. Technically, Optimism’s AttestationStation and EAS make it straightforward to collect and query such data. Legion could run off-chain scripts that regularly pull all relevant attestations and recompute scores, or even deploy a semi-decentralized compute process (like a reputation subgraph on TheGraph or an Optimism fault-proof program) to calculate scores from the attestation graph. In the near future, we might see specialized reputation networks (perhaps using EigenTrust or PageRank on social graphs) – Legion should be prepared to either integrate or become one, ensuring its algorithms remain **state of the art and credibly neutral**.

Example of a rich reputation graph: Optimism’s AttestationStation allows community members to make statements about an address (e.g. participation in a DAO, event attendance, trust scores). Legion could both contribute to and draw from such open attestation networks to compute decentralized reputation ⁹ ⁴¹ . In this illustration, each badge or tag (skill, membership, trust rating) is an attestation that can feed into an overall reputation score.

- **Soulbound Tokens and Non-Transferable Badges:** While we touched on SBTs in the standards section, it’s worth noting how they play into on-chain mechanics. Legion could issue *non-transferable badge NFTs* for certain achievements as a complement to its numeric score. For instance, a user who has meaningfully contributed to 5 successful token launches via Legion could get a “Legion Vanguard” badge. These badges are easily readable on-chain (any contract can check `balanceOf(address, badgeID)` to see if a user has it) and can be used for gating or rewards (a DAO might e.g. airdrop tokens to all “Vanguard” badge holders). Importantly, because they are soulbound, they tie reputation to the identity and cannot be sold or traded – preserving the **“earned” nature of reputation** ⁵³ . Technical feasibility for this is high today: ERC-1155 or the proposed ERC-5727 standard can be used for soulbound badges ⁵⁴ . The challenge is managing revocation (if someone abuses their status, can the badge be stripped?) which might be handled by having the badges expire or be re-issuable each year based on continued good behavior. Legion could implement an **attestation-to-badge pipeline**: once certain criteria are met (as recorded by on-chain attestations or off-chain logs), an automated contract mints the badge to the user. This provides a clear, **on-chain signal of reputation** that protocols can respond to instantly (without needing to integrate Legion’s API). For privacy, these badges should be relatively broad (e.g. category of contributor) rather than encoding detailed metrics. In combination with ZK proofs, one could even imagine a user proving ownership of a

badge without revealing their address (zk-SNARKs for proving membership in the set of badge holders). Summarily, using SBTs judiciously can amplify Legion's presence in on-chain activities – every time a user's wallet is viewed, their Legion-issued badges are a visible “watermark” of their Web3 reputation.

- **Synergies with Identity/Privacy Tech (BrightID, Proof of Humanity, etc.):** Legion should also integrate with or support other identity-proof systems, as they are complementary. For example, **Proof of Humanity (PoH)** provides an on-chain registry of unique humans. If a user is verified on PoH, Legion can boost their trust (reducing sybil concerns) or simply import that fact as an attestation. Similarly, **BrightID** (a social graph-based uniqueness system) or **Gitcoin Passport** (which uses multiple verifications to assign a trust score) can be both data sources for Legion and beneficiaries of Legion's data. Gitcoin Passport, for instance, aggregates many “stamps” (verifications like Twitter, phone, GitHub) to produce a score for sybil resistance ⁴⁵ ⁵⁵. Legion could feed its own scores as a stamp into Passport (e.g. “Legion score above 500” gives you X points in Passport's system), enhancing quadratic funding defenses. Conversely, users who have a high Passport score could be treated as more trustworthy input for Legion. The technical aspect is mostly about data exchange and possibly **standard schemas** – e.g. both Passport and Legion could use the same EAS schema for a “humanity score” attestation so that one can accept the other's verification easily ⁵⁶ ⁴⁵. By collaborating rather than competing with such systems, Legion fits into a **network of interoperable reputation and identity providers**, each reinforcing the other. In a realistic near-term scenario, Legion might partner with Optimism's identity initiative (which already integrated Passport and EAS on OP Mainnet) ¹⁰ so that **Legion's reputation scores are one of the default data points available to any OP Chain dApp**. This deep synergy would cement Legion's role at the infrastructure level.

In summary, combining ZK proofs with open attestations and careful token design enables Legion to offer **trust with discretion**. The technology to do this is rapidly advancing: for example, **Polygon ID** uses zk proofs for ID credentials, **Sismo** issues zk-based badges, and EAS provides a live attestation network. Legion should adopt these into its architecture now, as it will make the platform **more secure (no leakage of personal data), more decentralized, and easier to integrate**. A focus on privacy and decentralization will also earn goodwill in the community, avoiding the critique that “Legion is a centralized oracle of reputation.” Instead, Legion will be seen as the orchestrator of a broad, privacy-preserving reputation web, which is exactly the kind of structural importance that lasts.

Adoption Strategies as Infrastructure (DAOs, L2s, Public Goods)

Even the best technology can languish without adoption. For Legion to become *structural infrastructure*, it needs strategy in how it onboards key partners and communities in both Web3 and Web2. The following approaches focus on **making Legion indispensable but unobtrusive** – ingraining it into ecosystems in a way that is genuinely helpful (not hype or pay-to-play):

- **Integration with DAO and Developer Platforms:** Target the platforms where communities gather and make it trivial for them to use Legion. For instance, Legion could build a plugin for **DAO management platforms** like Aragon, DAOstack, or CharmVerse that provides a “reputation dashboard” of members. If a DAO can click a button and see all members' Legion Scores, plus perhaps auto-create voting weights from them, it saves them effort in building their own reputation system. Offering this for free (or as open-source) would encourage DAOs to adopt it. Another angle is to embed into **developer collaboration platforms**: many Web3 projects coordinate on Discord, Discourse, or Telegram. Legion can release open bots or widgets for these – e.g. a Discord bot that can be invited to a server and will label users with their Legion

reputation tier, or respond to commands like `!legion @user` to fetch their contributions. These sorts of tools *get Legion's concept in use organically*. Once a few large DAOs or hacker communities find it useful to identify top contributors via Legion, others will follow. Technically this is straightforward (it's essentially just using Legion's API in different frontends), but the key is outreach: **Legion should run pilot programs or bounties** with a handful of prominent DAOs to prove the value. For example, a grant could be given to integrate Legion into GitcoinDAO's contributor tracking or into BanklessDAO's member profiles. Those success stories (improved onboarding, reduced sybil proposals, etc.) can be showcased to drive broader adoption.

- **Partnerships with Layer-2s and Rollup Providers:** Gaining adoption at the infrastructure level could mean partnering directly with L2 projects or middleware. For instance, an L2 like **Base or Polygon** might be interested in offering a better identity layer to its dApps. Legion could propose to be the **reputation service embedded in an L2's developer stack**. This could work akin to how Chainlink is often provided as the default oracle network for many chains. Concretely, Legion could deploy nodes or services in those ecosystems such that any contract or dApp on the L2 can query reputation easily (perhaps via a precompile or a well-known contract address). Optimism's approach of including EAS in the OP Stack at genesis is a model ¹⁰ – Legion could advocate for inclusion of a "reputation module" in similar stacks. Even beyond technology, **co-marketing partnerships** with chains can help: if Arbitrum (which Legion already supports ⁵⁷) were to officially mention Legion as a solution for projects needing sybil resistance or community curation, that endorsement would drive usage. Public goods networks like **Gitcoin, Optimism Collective, or RetroPGF programs** are also prime targets – they *need* reputation systems to allocate funds fairly. Legion could volunteer to provide **infrastructure for grant programs**: imagine Gitcoin integrating Legion Scores alongside their Passport to decide grant quadratic weights, or Optimism using Legion to identify contributors to reward in its retroactive funding rounds. By aligning with these missions, Legion gains not only adoption but a positive narrative (as an enabler of fair, human-centric outcomes in Web3). The strategies to achieve this include building specialized features (e.g. a version of Legion Score tuned for open-source contributions for Gitcoin) and making integration as **low-friction as possible (robust APIs, clear docs, even technical support from Legion's team)**.

- **Open Governance and Decentralization to Build Trust:** To be adopted as common infrastructure, Legion should consider **progressive decentralization** of its own governance or at least transparency of its methods. DAOs and chains will be wary to rely on a black-box controlled by one company. Even if the algorithms are complex, Legion can publish a **whitepaper or audits** of its scoring mechanism (to the extent possible without enabling gaming) and commit to community input. Down the line, Legion could introduce a governance token or community board that oversees updates to the reputation formulas. This kind of openness will make large ecosystems (like Ethereum's core community or big DAOs) more comfortable embracing Legion as a dependency. Technically, some parts of Legion could be decentralized – for example, using a **smart contract for calculating a portion of the score (like an on-chain reputation metric)** or open-sourcing the code that fetches and weights data. The **Optimism Collective's model of a "Citizens' House" using reputation** hints that *governance will move toward identity & reputation-weighted systems* ⁵⁸. If Legion is visibly moving in that direction alongside the community, it stands to become the default solution rather than a proprietary tool.

- **Offer as Public Good / Minimal Rent Extraction:** For critical adoption, Legion should make its basic reputation layer **free or extremely low-cost** for others. If every integration requires paying Legion fees or buying a token, uptake will be slow and suspect (viewed as a money grab). Instead, Legion can differentiate by being **open-access infrastructure** (at least at the data

layer). Perhaps AbsurdSenapiii Labs funds the operation via other means (grants, advanced premium services, etc.) while providing core reputation queries and credentials to anyone permissionlessly. A model here is **Ceramic Network and IDX** – they provide decentralized identity data storage openly, and projects like Gitcoin Passport leverage it to store credentials ⁵⁹ ⁶⁰. Legion could similarly publish user rep data to a public network (Ceramic, or simply as on-chain attestations) which anyone can read at no cost. Monetization (if needed) can come from value-added services (e.g. custom analytics for VCs, or enterprise integrations) rather than charging dApps for each reputation check. By positioning as a **public good** for the ecosystem, Legion is more likely to be picked up by DAO tooling, wallets, and so on, because it won't impose a burden on their users. In practice, this might involve Legion **joining public goods funding efforts** (applying for grants from Ethereum Foundation, Gitcoin, etc. to subsidize its development in the open). This both helps with resources and signals to the community that Legion intends to be *infrastructure for everyone*, not a closed profit center. Given the prompt to focus on influence rather than monetization, this strategy is in line: Legion's structural importance will come from ubiquity and trust, which in turn grows long-term value (even if short-term it forgoes some revenue opportunities).

- **Subtle Influence via “Powered by Legion”:** Adoption can be accelerated by branding strategy as well – which leads into the low-key branding approach. Legion should aim for the kind of integration where *people might not even realize they are using Legion*, but the benefits are felt. For example, when a user joins a new DAO and instantly their past contributions (fetched via Legion) are recognized, the DAO tool might just show “Profile verified by Legion” in fine print. This is akin to how many websites quietly show “Secured by Cloudflare” or how software might note “Powered by XYZ Engine” in the about page. Legion can pursue co-branding where **its name appears as a trust mark** rather than a headline. If Legion becomes the backend for “Login with Ethereum” flows (providing enriched profiles), a small Legion logo or watermark could appear on the login modal to build brand awareness without overwhelming the user experience. Over time, *Legion's reputation itself will grow* (i.e. projects will recognize “Legion Score” as a quality mark, similar to how “FICO score” in TradFi is known). Achieving that requires consistency and presence in the right places: **wallets and identity managers**. Imagine if MetaMask or Ledger Live could display your Legion reputation or let you share it – being integrated there (even if only as an optional module) would be huge for legitimacy. Securing such integrations likely means **providing SDKs and working with wallet dev teams**, perhaps offering them something in return like analytics on user needs or just the appeal of added functionality for their users. The key for adoption is that Legion's value should speak for itself (improving security, reducing sybil attacks, making communities stronger). If that holds, even low-key exposure will lead to demand (“Why isn't our platform using Legion? We want those benefits too.”). Thus, Legion's strategy should be to embed in critical points of the user journey (login, profile setup, DAO membership, DeFi lending) and quietly ensure things go smoother with Legion – over time making it indispensable.

Low-Key Branding and “Watermarking” by AbsurdSenapiii Labs

While the primary goal is integration and utility, there is still an interest in credit for the creators (AbsurdSenapiii Labs) without resorting to hype. A **low-key branding approach** can ensure the lab's name and Legion's identity become known in the right circles:

- **“Powered by Legion” Footprints:** As mentioned, including a discreet “Powered by Legion” or Legion's logo in partner UIs is a way to mark the technology's presence. For example, a DAO's dashboard might have a small Legion emblem next to a user's reputation score, or a login screen could say “Login with Ethereum (Legion enhanced)” in tiny text. These watermarks should be

subtle in color and size, so as not to distract from the host platform's branding. The impact is cumulative; as multiple dApps display the mark, users start to notice that *Legion is everywhere*. This is similar to how many websites show a trust badge like "Secured by SSL - Let's Encrypt" or how some social platforms show an icon for verified credentials. The trick is finding placements that **convey trust** (since Legion's brand should connote "this user is credible") and not self-promotion. Over time, **Legion's brand becomes synonymous with trusted reputation data**, which reinforces its adoption further.

- **Open Source and Research Contributions:** AbsurdSenapiii Labs can increase its prestige by publishing research, standards, and open-source code related to Legion. For instance, authoring an EIP (Ethereum Improvement Proposal) or W3C draft about a "standard reputation schema" or an "on-chain credential format" would permanently tie the lab's name to the evolution of the field. This is a form of branding in the technical community – being cited in specs and referenced in academic papers. It's low-key in that it's not a marketing stunt but a genuine contribution. If Legion's algorithms or protocols are open-sourced, the GitHub repo (under AbsurdSenapiii Labs' organization) will attract developer attention, again quietly spreading awareness. Many successful Web3 projects (e.g. OpenZeppelin, IPFS by Protocol Labs) built huge goodwill and name recognition by open-sourcing core tech. AbsurdSenapiii Labs can do the same, releasing perhaps the **Legion scoring engine** or the **Legion API client** as open libraries. Developers using those libraries will see the Lab's name in docs and code comments, which is subtle but effective mindshare.
- **Maintaining a Neutral, Non-Shilling Tone:** Part of low-key branding is avoiding overt hype. Legion's communications should focus on the value and technical robustness, not on "to the moon" rhetoric. Case studies, technical blogs, and developer documentation can carry the brand in a professional way. For example, publishing a **case study with CookieDAO or Kaito (as mentioned in the Medium article) about how they built on Legion** ⁶¹ ⁶² will both showcase Legion's utility and mention AbsurdSenapiii Labs as the innovator. The lab could also present at industry conferences (e.g. DEVCON, DWeb, ReFi events) about reputation in Web3 – these talks would be content-driven but naturally promote the brand by association. A measured approach builds respect among the exact audience who will decide on integrations (developers, architects, DAO leaders).
- **Branding Through Community Trust:** AbsurdSenapiii Labs might consider establishing a **reputation of its own as a public-goods-oriented, security-conscious team**. Things like releasing transparency reports, undergoing security audits, and engaging in community governance (perhaps the lab's members could become delegates in DAOs, contributing constructively) will brand the lab as thought leaders in decentralized reputation. If the community sees "AbsurdSenapiii Labs" on a forum giving insightful advice on integrating reputation or on Twitter sharing research on sybil attacks, that is subtle branding – associating the name with expertise and goodwill. The LinkedIn posts by the lab indicating shifts toward sustainable, repeatable execution ⁶³ and transparency reports show a move in this direction. Continuing on that path (e.g. regular updates on Legion's impact, lessons learned from data, etc.) will accumulate a positive aura around the brand without needing flashy ads.

In implementing low-key branding, it's important that Legion's presence feels like a **quality stamp** rather than an ad. The **goal is to have others proudly mention Legion**: for instance, a DAO announcing "We've improved our onboarding by using Legion's reputation scores" (implicitly endorsing the lab's work). This kind of word-of-mouth, where **the users become the marketers**, only happens if the product is genuinely solving problems. Thus, AbsurdSenapiii Labs should prioritize Legion's real-world impact; the branding will naturally follow. Just as "Intel Inside" became ubiquitous because people

valued reliable CPUs, “Legion Inside” could become a quiet standard for reliable reputation across Web3 and Web2.

Conclusion

Legion has a timely opportunity to become the de facto reputation layer bridging Web3 and Web2. The technical pathways discussed – from embedding in DeFi and DAO frameworks, to offering Web2 logins and verifiable credentials, to aligning with DIDs and on-chain attestations – are all implementations that are *realistic with today's technology*. By combining these with privacy-preserving ZK techniques and a truly open integration model, Legion can overcome the fragmentation of trust and identity in crypto. The steps forward involve deep technical integration (APIs, smart contracts, standards) and proactive collaboration with other platforms and communities.

Crucially, the approach must remain **infrastructure-first**: Legion succeeds by making others succeed (safer platforms, fairer fundraises, more human-friendly dApps). If AbsurdSenapiii Labs focuses on that mission – providing reputational legitimacy as a service – Legion’s influence will grow organically. Already we see signs of this future: multi-chain support is underway ⁵⁷, and projects are building on Legion’s infrastructure (Cookie, Kaito) ⁶¹. Following through with the integrations and strategies detailed above will ensure that in a few years, **Legion’s reputation network is woven into the fabric of both decentralized protocols and traditional online services**. At that point, Legion won’t need to tout its importance – it will be apparent, as countless systems quietly rely on that trust layer, and users come to expect that a **Legion credential** is part of their digital identity wherever they go. In summary, a technically grounded, standard-aligned, and community-driven expansion will make Legion not just a platform, but a **foundational layer of the emerging trust web** across Web3 and Web2.
