

Legion Credibility Platform Wishlist & Roadmap

TL;DR (Key Themes & Priorities)

- **Key Themes:** Strengthen Legion's data-driven reputation system, enforce long-term accountability for both investors and projects, enhance transparency/compliance, and build tools that align communities with founders. These themes reinforce Legion's mission as a **credibility layer** – ensuring token allocations favor true contributors over speculators ¹ ².
- **Highest-Leverage Wins:** Quick improvements like **making Legion Scores more transparent to users** (showing sub-scores and how to improve them) and **integrating richer contribution data** (e.g. on-chain activity, social/GitHub metrics) offer outsized impact. They would immediately level up the credibility signal of Legion's merit-based access ³ ⁴. Equally, **better matching tools** to connect value-adding investors with relevant projects can maximize "value per dollar" raised ⁵ ⁶ – all achievable with moderate effort.
- **Hardest Long-Term Bets:** Ambitious plays include **decentralized reputation infrastructure** (community-governed scores or soulbound credibility tokens) and **privacy-preserving compliance** (using zero-knowledge proofs for KYC/credibility). These will demand new primitives and broad coordination. Additionally, **global regulatory expansion** (e.g. U.S. compliance) is a heavy lift socially and legally, but critical for Legion to become a ubiquitous credibility standard in crypto fundraising.

Easy (E) Tier – Quick Wins for Credibility

Investor Score Transparency & Feedback (E)

Legion should expose the components of a user's **Legion Score** and provide clear feedback. Today, each user has a composite score (0–1000) with sub-scores (e.g. social influence, technical skill, on-chain activity) and even "achievements" earned ⁷. Making these factors visible on the user's profile would build trust in the scoring system and guide users on how their score is calculated. For example, an investor could see they have a high technical score but low community score, along with tips to improve (such as participating in forums or social channels). This demystifies the credibility scoring and reinforces Legion's meritocratic ethos that *"what matters is how you've contributed"* ¹ rather than how much money you have.

In practice, this is a trivial UI enhancement pulling existing data. The platform can display a **score breakdown (pie charts or bars)** for each contribution category and list any badges or notable achievements earned by the investor. A simple tooltip or note can explain why these factors matter for credibility (e.g. *"Active open-source contributors are highly valued by projects"*). This improvement should be quick to implement and immediately aligns with Legion's mission by nudging users toward **value-adding behavior** (since they'll know what counts). **Difficulty: Easy** – it's largely a frontend update reading from data already collected.

Contributor Education & Onboarding Guides (E)

To cultivate high-quality investors, Legion could introduce an onboarding guide or mini-education center about being a “credibility-driven” contributor. New users would get **tips to boost their Legion Score** – for instance, prompts to connect their social accounts, verify identity, link a GitHub (for developers), and join community discussions. This can be delivered as a checklist or tutorial when a user signs up. Short term, this is mostly about content: explaining that participating in governance, contributing expertise, or holding tokens long-term will positively impact their reputation ⁸. By educating users, Legion effectively **pre-filters for mission-aligned investors** who understand that *long-term support and real involvement* are rewarded over quick flips ⁹ ¹.

Implementation could be as simple as a “Legion Credibility Academy” page or a FAQ and checklist integrated into the dashboard. For example: “*Complete your profile (add all your wallets, social links) – 5 min*”, “*Join a project’s community call – 30 min*”, “*Earn an achievement by contributing to an open-source repo*”, etc. Progress bars or **gamified prompts** can turn this into a quick win. Since this doesn’t require heavy engineering (mostly creating content and a UI modal), it’s an **Easy** lift. It pays off by **standardizing what “value-add” means** for users, creating a culture where investors actively seek to raise their credibility in genuine ways – directly supporting Legion’s credibility layer mission ².

Medium (M) Tier – High-Impact Feature Additions

Richer Data Integration for Legion Score (M)

To enhance Legion’s reputation accuracy, the platform should integrate **broader data sources** into the Legion Score. Currently, Legion considers factors like users’ social media activity, GitHub commits, and on-chain transactions ⁴. Expanding this with additional signals will paint a fuller picture of an investor’s contributions. For example, Legion could ingest **governance participation** (did the user vote on DAO proposals or hold governance tokens?), **community engagement** (activity on Discord/Discourse forums or contributions in DAO projects), and **credential verifications** (such as holding POAPs for attending industry events or completing courses). Each data point bolsters the credibility signal: e.g. a user who actively votes on Snapshot and holds developer NFTs from hackathons is likely a committed community member.

Technically, this means partnering with APIs or networks: for instance, using Snapshot’s API for governance data or Gitcoin Passport for verified achievements. Legion could also leverage **on-chain credentials** (Ethereum Attestation Service or similar) to verify contributions. Incorporating these inputs would address the industry challenge of “**no reliable way to assess investor quality at scale**” by widening what is measured ¹⁰. Founders would get an even more merit-based filter, knowing the Legion Score accounts for many dimensions of value-add. This feature requires moderate effort – integrating new data sources and updating the scoring algorithm – hence **Difficulty: Medium**. It directly advances Legion’s credibility mission by ensuring the **Legion Score 2.0** is comprehensive and harder to game, spotlighting true “**project-aligned investors and contributors, not bots or empty wallets**” ⁴.

Post-Investment Accountability Mechanisms (M)

Legion should build features to track and reward investors’ behavior **after** a token sale, strengthening accountability. The idea is to adjust an investor’s Legion Score based on their *post-raise actions*: Did they **hold or stake** the tokens (showing long-term belief), or did they immediately dump their allocation? Are

they actively participating in the project's ecosystem (e.g. joining governance, providing liquidity, building on the project)? Legion already plans dynamic scores where "reputation scores change based on how investors support the projects they invest in, disincentivizing short-term, value-extractive behaviors" ⁷ . This feature would operationalize that principle.

In implementation, Legion can integrate with the project's token smart contract to monitor each investor's holdings over time or require the investor to link their wallet post-sale. For example, 3 months after a sale, Legion could check what percentage of their tokens an investor still holds or if they've been active in governance. Investors who **dump early** might see their score slashed significantly ⁹ , while those who remain engaged maintain or even boost their credibility. A dashboard for investors could show a "*trust bonus*" for holding tokens and a warning if a quick exit will hurt their score. Founders benefit by knowing future allocations favor those proven to stick around. **Difficulty: Medium** – it needs some on-chain data analytics and integration per project, but these are well within reach. Crucially, this reinforces Legion's credibility layer as not just a one-time gate, but a persistent measure encouraging **long-term alignment between investors and projects** ⁹ ¹¹ .

Investor-Project Matching Engine (M)

To maximize the "value per dollar" for fundraising, Legion can introduce a smarter **matching engine** that pairs projects with the most relevant investors. Currently, Legion's two-way opt-in system lets investors create detailed profiles (e.g. their typical check size, main value-add) and founders can review these profiles before accepting funds ¹² . Building on this, a matching feature would automatically highlight ideal candidates: for instance, if a project is a DeFi protocol, the system might flag investors with high technical scores or DeFi usage history. Founders could set criteria or weights (e.g. "prefer investors with governance experience" or "must have contributed code on GitHub"), and Legion would sort or recommend applicants accordingly ¹³ . This streamlines what might otherwise be a manual review of profiles, especially as scale increases.

A possible implementation is a "**match score**" or filter in the project's dashboard: as investor applications come in, founders see a ranked list or categories (developers, community builders, influencers, etc.) with each investor's key credibility stats. The engine could also notify high-score investors about projects aligning with their interests ("*You have a top Legion Score in NFTs – Project X might benefit from your expertise.*"). By algorithmically aligning communities with builders (as Legion and Kraken envision ¹⁴), Legion ensures **funds flow to true believers and domain experts**, not just whoever clicks fastest. This is a moderate effort feature – it requires data science and a slick UI, but no fundamental R&D – so **Difficulty: Medium**. The impact on Legion's mission is significant: it concretely realizes the vision of *allocating tokens to loyal community members and project-aligned investors* ¹⁵ , making each raise more strategic and credibility-driven.

Achievements and Soulbound Credibility Badges (M)

Legion can amplify its reputation system by introducing **achievements and badges** that recognize specific investor contributions. The platform already notes user "achievements" during onboarding (e.g. highlighting a user's main value-add or milestones) ¹⁶ ; formalizing this into a badge system would gamify positive behavior. For example, an investor who has contributed to multiple open-source repositories might earn a "**Open Source Champion**" badge, while a user who has held all their token allocations for over a year gets a "**Diamond Hands**" badge. These badges can be **soulbound NFTs** (non-transferable tokens)

minted to the user's wallet, serving as portable proof of credibility. They would appear on the user's Legion profile and could even be verified externally on-chain.

Why is this important? It provides **quick trust signals** to project teams – a founder seeing a “Community Moderator” badge on an applicant knows this person is experienced in community building, for instance. It also motivates investors to earn and maintain these badges, aligning their behavior with Legion's long-term values. Implementing this would require defining criteria for each achievement and automating the badge awards (for instance, detecting when an investor's on-chain activity meets the threshold for a given badge). There is precedent in crypto for using NFTs as reputation markers (e.g. POAPs for attendance, Gitcoin kudos, etc.), so Legion would be extending that concept to fundraising credibility. **Difficulty: Medium**, as it involves smart contract work for minting badges and some back-end logic, but it's not fundamentally new tech. This feature directly bolsters Legion's credibility layer by **celebrating verifiable contributions** – turning an abstract score into tangible credentials that both investors and projects can rally around.

Unified Identity & Multi-Wallet Support (M)

To ensure Legion captures an investor's full reputation, the platform should support **linking multiple wallets and identities** under one profile. Crypto power-users often operate on several chains and addresses; if Legion only considers one wallet, it might miss part of their track record. An improvement is to let users connect all relevant wallets (e.g. an Ethereum address, a Solana address, etc.) and aggregate their on-chain contributions. This unified identity approach, combined with the existing KYC uniqueness check ¹⁷, means a user is evaluated on *all* their activities. For instance, an investor might use one address for DeFi trading and another for NFT collecting – both facets would count toward their Legion Score once linked.

Implementation involves allowing multiple wallet connections during onboarding or in the profile settings. The platform would merge data from each verified address into one reputation profile (perhaps even showing sub-scores per chain or domain). Since Legion already lets users connect social accounts and a wallet ¹⁸, extending to several wallets is a logical next step. This is especially crucial as Legion spans multiple blockchains; it prevents users from needing separate accounts per chain and thwarts attempts to silo behavior to game the score. The effort here is moderate – handling the mapping of identities and updating score calculations – thus **Difficulty: Medium**. The payoff is a more **holistic and accurate credibility assessment** for each person. It reinforces that Legion is an identity-based reputation layer (one person, one reputation ¹⁷) rather than per-wallet, making sybil attacks even harder and ensuring genuine contributors get full credit for their diverse on-chain footprints.

Hard (H) Tier – Foundational Upgrades to the Credibility Layer

Decentralized Identity & Verifiable Credentials Integration (H)

As Legion grows, integrating **decentralized identity (DID)** and **verifiable credentials** will strengthen its credibility system with user-owned, tamper-proof data. Currently, Legion relies on traditional KYC and its internal algorithms (including EigenTrust) to verify unique, real participants ¹⁷. In the future, Legion could incorporate DIDs (from platforms like Ceramic or Spruce) so that users can carry a portable identity, and accept **verifiable credentials** (VCs) issued by trusted third parties about that user's contributions. For example, a DAO could issue a credential attesting that “*User X was a top 10 contributor in our community for 2025*”, or a hackathon organizer could vouch “*User Y won a prize in our DeFi hackathon*”. Users would store

these credentials in their wallet or identity hub and **permission Legion to read them** to boost their Legion Score. This aligns with the crypto ethos of users owning their reputation data, rather than it being siloed on Legion's servers.

Implementing this is complex. Legion would need to support reading and verifying credentials (which might be signed JSON documents or on-chain attestations) and incorporate them into the score computation. It could start by **issuing its own verifiable credential** to users – for instance, a credential for a user's Legion Score or tier that others can verify independently. Over time, Legion could participate in an identity network where **contributions are trustlessly verified**, reducing reliance on centralized checks. This is labeled **Difficulty: Hard** because it requires adopting emerging standards and possibly developing new infrastructure for credential exchange. However, the benefit is high: it future-proofs Legion as *the* credibility layer by making its reputation **interoperable** across Web3. It also enables privacy improvements – users could selectively disclose only the credentials needed for a given project, enhancing trust without excessive data sharing. In sum, DIDs and VCs would move Legion closer to a decentralized, user-centric reputation system, elevating the credibility of both investors and the platform itself.

Community Endorsements & Trust Graph (H)

Legion can leverage its growing community to enhance the credibility scoring via **peer endorsements and a trust graph**. In addition to algorithmic scoring, allowing credible members to vouch for others introduces a human layer of validation. The concept is that investors or community leaders with high Legion Scores could **“endorse” or recommend** new investors (much like LinkedIn recommendations, but on-chain or within the platform). In fact, the Legion Score already considers “recommendations supporting” an investor ¹⁹ – this feature would formalize that process. For example, a well-regarded DeFi developer on Legion might endorse an up-and-coming contributor by attesting to their skill or character. These endorsements, especially weighted by the endorser's own credibility, would feed into a **web-of-trust** model (similar to how EigenTrust computes trust via networks). Over time, a graph of endorsements forms, which Legion can analyze to detect clusters of genuine trust vs. potential collusion.

To implement this, Legion could introduce an **endorsement feature** in profiles: a user can request a recommendation from someone they've worked with, or a project founder can leave feedback for an investor post-raise. Each endorsement could be an on-platform signed message or even an on-chain attestation. The scoring algorithm would give extra weight to endorsements from users with proven high credibility (preventing a sybil attack of fake accounts endorsing each other). This is technically and socially complex – **Difficulty: Hard** – because it requires careful design to avoid abuse (e.g. quid-pro-quo endorsements) and potentially significant changes to the scoring logic. However, done right, it directly reinforces Legion's mission. It harnesses community insight to answer the subtle question **“who is truly value-add?”** in ways data alone might miss. By capturing qualitative reputation in a structured way, Legion strengthens its position as a nuanced credibility layer where **social proof and trust networks** complement raw metrics ²⁰ ² .

Project Transparency & Accountability Features (H)

Just as Legion holds investors accountable, it should introduce features to **keep projects accountable** and transparent to their new communities. One idea is a **post-fundraise transparency dashboard** for each project. After a token sale, the project team would be prompted (or required under Legion's terms) to provide periodic updates – e.g. fund usage reports, development progress, milestone achievements, and

any changes to their roadmap or tokenomics. This aligns with EU regulations (MiCA) requiring updated whitepapers for material changes ²¹, and Legion could facilitate compliance by hosting these updates in one accessible place. Investors who participated via Legion would thus have a clear line-of-sight on the project's execution, building trust that goes beyond the raise.

Another feature is an **investor feedback mechanism**: perhaps a private rating or review that participants can give after a certain period, reflecting if the project met expectations. Legion might aggregate this (e.g. "Project X has an 8/10 credibility score from its investors six months post-raise"), which could inform other users or even be factored if the team uses Legion for future rounds. Combined with Legion's due diligence on projects upfront, these measures enforce a culture of accountability. As noted at Solana Breakpoint, a key challenge in ICOs was "little accountability for many projects" ¹⁰ – Legion can differentiate itself by not just vetting initially but tracking outcomes.

Implementing a updates dashboard and feedback loop is primarily a product design and coordination effort (ensuring teams actually post updates). It may also involve smart contract escrow or milestone-based releases in the future (a Very Hard extension) – for now, simply creating the **infrastructure for transparency** is the focus. This is **Difficulty: Hard** because it treads into softer territory of project management and disclosures, and it must be handled carefully to avoid legal liability or undue burden on teams. Still, even a voluntary but visible system would significantly advance Legion's mission. It completes the credibility layer by holding *projects* to a higher standard of honesty and engagement, not just investors. In the long run, this two-sided credibility (investors with Legion Scores, projects with transparency scores) fosters a healthier ecosystem where **both sides are accountable** ², echoing the original ethos of fair and community-driven ICOs.

Investor Lock-Up Incentives for Long-Term Commitment (H)

To further align incentives, Legion could offer **token lock-up or vesting options** for investors as part of the sale terms. This feature allows (or requires) certain allocations to be subject to vesting schedules, encouraging investors to stay for the long haul. For example, a project might let retail investors choose: *Option A*: buy tokens with no lock-up, or *Option B*: buy with a 6-month lock-up in exchange for a bonus (more tokens or a slight discount). Investors who truly believe in the project's vision might opt for the locked option, signaling their commitment. Those who take the immediate liquidity route might get less allocation or no bonus. Legion can facilitate this by building smart contract support for timelocked token distributions and by integrating the choice seamlessly into the purchase flow.

This mechanism ties directly into credibility: a participant willing to time-lock their investment demonstrates credibility (literally putting their money where their mouth is). It deters opportunists looking for instant flips, complementing the reputation system's goal of "**assembling a retail army**" of long-term supporters ⁹. Implementing lock-ups is non-trivial – it involves additional contract logic and complexity in token distribution, as well as clear communication to users – so **Difficulty: Hard**. It may also require standardizing how vesting is handled across different projects. However, this feature is already common in private rounds (founders and VCs often have vesting); extending it to public sales via Legion would import a TradFi-like discipline into ICO 2.0 ²². In short, lock-up incentives would be a powerful tool for Legion to **reward patience and conviction**: credible investors get better terms, projects get a stable holder base, and the overall token launch is less prone to immediate dumping – reinforcing the credibility and sustainability of the fundraising outcome.

Very Hard (VH) Tier – Big Bets & Visionary Moves

Global Multi-Jurisdiction Compliance Support (VH)

Legion's credibility as a fundraising platform rests heavily on regulatory compliance and broad accessibility. A long-term, very challenging goal is to **expand Legion's compliance framework globally**, so projects anywhere can raise from investors anywhere, within legal bounds. Today, Legion is pioneering MiCA-compliant offerings in the EU ²³ and partnering with an exchange (Kraken) to reach millions under a regulated umbrella ²⁴. The wishlist goal is to add support for other jurisdictions: for instance, **U.S. regulatory compliance** (perhaps via Reg A/Reg CF offerings or working with the SEC if rules soften) and compliance in key markets like Asia. This could mean obtaining licenses or partnering with licensed entities (brokers, crowdfunding portals) in each region. It also means adapting the platform's KYC/whitelist process to handle different investor categories – e.g. distinguishing accredited U.S. investors, retail EU investors under MiCA, etc., and showing each user which sales they are eligible for.

The importance to Legion's mission is clear: *equal opportunity access* cannot be fully realized if large segments of the global community are excluded by regulation. By tackling the hardest legal challenges, Legion solidifies itself as the **credibility layer that also plays by the rules** everywhere. A user should trust that if a sale is on Legion, it's legally above-board in their jurisdiction, with all required disclosures and protections ²⁵. Suggested steps include continuing dialogue with regulators (as Legion's founders have with the SEC on disclosure standards ²⁶), building an in-house compliance team, and modularizing the platform to plug in different compliance modules per region. This is **Difficulty: Very Hard** – it's less about coding and more about **deep coordination** with legal systems, policymakers, and possibly inventing new compliant offering models. Success would profoundly differentiate Legion: it becomes the first truly **global, compliant token launchpad**, enhancing credibility by not only vetting investors and projects, but also by respecting every relevant law. In the long term, this unlocks a massive, trustable participation pool and cements Legion's role as the legitimate bridge between traditional finance standards and the decentralized fundraising world ²² ¹⁴.

Community-Governed Reputation Protocol (VH)

In the spirit of decentralization, Legion could evolve its credibility platform into a **community-governed reputation protocol** – an open system managed by its stakeholders. This is a bold vision: rather than Legion's team alone setting the scoring criteria or controlling the data, the broader community of credible investors, projects, and perhaps a governing token would have a say. For example, Legion could release its scoring algorithm and data models as open source and allow expert community members to propose improvements (e.g. adjusting weightings or adding new reputation signals). A decentralized autonomous organization (DAO) could be formed, where Legion token holders vote on these proposals or on policies like what data to include or how to handle edge cases. Over time, reputation issuance (Legion Scores or badges) might be done via smart contracts with on-chain attestations, making it a public good that any platform can verify or even contribute to. Essentially, Legion could seed the **"Credibility DAO"** for Web3 fundraising.

The rationale is that credibility in a decentralized ecosystem might itself need to be decentralized to be trusted at the highest level. A community-driven model reduces concerns of bias or opacity – if everyone can inspect and influence the rules, the **credibility layer stays credible**. It also helps Legion scale as an **industry standard**; other launchpads or networks might adopt Legion's reputation protocol if it's open and neutral, extending its influence (imagine wallet profiles showing a "Legion reputation score" as a universal

metric). Achieving this is extremely challenging. It demands new infrastructure (perhaps issuing a token for governance), meticulous design to prevent governance capture or exploitation of the reputation system, and a gradual handover of what is currently a centralized service to a distributed community. It's definitely **Very Hard** in both technical and social terms. Yet, if accomplished, it positions Legion not just as a platform but as **the credibility infrastructure for Web3** – the backbone for “merit over money” in fundraising that many projects, exchanges, and communities could plug into. This would fulfill the boldest interpretation of Legion's mission: an open, self-sustaining credibility network that underpins on-chain capital formation, much like how Web3 projects envision decentralized versions of traditional institutions ²⁷.

Privacy-Preserving Credibility Verification (VH)

Another visionary feature for the long run is incorporating **privacy-preserving techniques** (like zero-knowledge proofs) into Legion's credibility assessments. One trade-off today is that being a credibility layer often involves collecting personal and activity data (KYC info, social links, transaction history) which can be sensitive. In the future, Legion could allow users to prove certain facts about their credibility *without* revealing all underlying data – enhancing privacy while maintaining trust. For instance, using zero-knowledge proof technology, a user might prove “I have a Legion Score above 800” to a smart contract or another platform, without exposing their identity or exact score breakdown. They could also prove attributes like “I have contributed to at least 3 GitHub projects” or “I did not sell any tokens from Project X for 6 months” in zero-knowledge. This would enable integrations where external dApps or sales could require a credibility proof on-chain, extending Legion's reach as a layer, but in a privacy-friendly way (no raw KYC data leaks).

Implementing this would likely involve advanced cryptography: Legion would need to generate zk-SNARK circuits or use protocols (e.g. identity nullifiers, selective disclosure credentials) to attest to reputation facts. The system might issue users a sort of “zk-ID” tied to their verified identity, so they can anonymously interact with certain processes while still constrained to one per person (similar in spirit to concepts like Semaphore or World ID, but focused on credibility traits). This is bleeding-edge and **Difficulty: Very Hard** – it requires R&D and perhaps collaboration with specialized projects in the zero-knowledge identity space. However, the payoff is keeping Legion at the forefront of trust technology. It would address concerns from privacy-conscious users or jurisdictions, and it fits Legion's narrative of bridging TradFi rigor with crypto innovation ²². By proving trustworthiness without compromising anonymity, Legion could attract a wider user base and facilitate use cases like truly decentralized token sales where on-chain contracts validate participant credibility via proofs, not centralized checks. In summary, while very ambitious, privacy-preserving credibility would solidify Legion's role as a **cutting-edge credibility layer** – one that empowers honest participants while respecting the decentralized ideal of minimal disclosure.
